

# FortVault + FortX Platform Architecture

High-level custody and product boundary. Dashed components are planned, not deployed flows.

## Primary product and custody path

## Current FortVault supporting components

## Custody dependencies and external execution

**Scope note** FortX financial operations and its FortVault API integration are planned. Current FortVault Exchange Processing is read-only exchange-account synchronization.

# Ownership and Trust Boundaries

Interpretation notes for the FortX + FortVault platform diagram

|                     |                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FortX clients       | End-user presentation only. They use FortX Backend APIs and do not call FortVault directly in the normal product flow.                                                                            |
| FortX Backend       | Current foundation includes identity/KYC integration, PostgreSQL, Redis, health, logging, and secret loading. The ledger, swaps, deposits, withdrawals, and FortVault integration remain planned. |
| FortVault Backend   | Business-control system of record for partner/workspace, customers, vaults, actions, approvals, and audit history. It is not a cryptographic signer.                                              |
| Custody Processing  | Execution owner for address generation, transaction construction, MPC coordination, broadcast, retries, and reconciliation. It owns its own execution state.                                      |
| MPC                 | Cryptographic boundary. A separate cluster is deployed per partner; key shares remain in MPC node storage. MPC independently validates signing authorization.                                     |
| Redis Streams       | Typed asynchronous transport. It is not the durable source of business or financial truth.                                                                                                        |
| Exchange Processing | Current scope is read-only exchange-account synchronization. Trading and exchange withdrawals are not part of the implemented scope.                                                              |
| External suppliers  | Keycloak, Sumsb, blockchain RPC/networks, external exchanges, and notification channels are separate supplier/trust boundaries.                                                                   |

**ISO evidence note**  
The diagram describes application architecture and intended trust boundaries. It does not prove live cloud configuration, TLS termination, network segmentation, backup effectiveness, patch compliance, monitoring, or operational access control. Those controls require separate production evidence.
